This Symposium is brought to you for free and open access by Scholarship@Vanderbilt Law. It has been accepted for inclusion in Vanderbilt Law Review by an authorized editor of Scholarship@Vanderbilt Law. For more information, please contact mark.j.williams@vanderbilt.edu.
Beginning around the year 2000, the cost of medical liability insurance for doctors sharply increased, allegedly doubling in some specialties. As a result, medical malpractice litigation has once again occupied center stage in public debate about tort reform.¹ Large jury verdicts are cited by insurers, physicians, and defense attorneys as unwarranted and corruptive of the medical system because they set the bargaining rate around which plaintiff and defense lawyers negotiate settlements.² One of the most commonly proposed remedies

¹ This research was supported, in part, by a Duke Law School research leave (Eugene T. Bost, Jr. Research Professorship of the Charles A. Cannon Charitable Trust No. 3) to the first author and by the Provost’s Common Fund to the first and third authors.

is a cap on the amount that can be awarded for general damages, often called “non-economic damages” or “pain and suffering,” following trial by jury.\textsuperscript{3}

Trial lawyers, consumer groups, and some independent scholars oppose these reforms.\textsuperscript{4} They say one problem is a high incidence of malpractice and consequent enormous economic losses for injured patients. They also assert that the reason for the increase in cost of malpractice insurance is poor decisions made by liability insurance companies and problems associated with recurrent downturns in the insurance industry business cycle, rather than underwriting experiences.

Systematic empirical data is needed about the many facets of this public policy controversy. Obtaining such information is difficult because much of the process of medical malpractice litigation has been beyond scrutiny. Typically, settlements are confidential and thus legislators, the general public, and researchers have been unable to obtain data about crucial questions bearing on the controversy. However, a closed claim database compiled by the Florida Department of Insurance sheds important light on these hidden processes. The data are available to the public and contain important information about many variables bearing on the litigation process, both settlements and jury verdicts. In the first article arising out of our research on the closed claims we developed profiles of the incidence of settlements at various stages of the litigation process, including claims settled without payments; changes in the seriousness of injuries associated with claims; the amounts of settlements; and the insurer's legal costs.\textsuperscript{5} The data involved cases settled from 1990 through 2003.

4. See BAKER, supra note 1, at 1 (arguing that there is a "medical malpractice myth" that "[m]edical malpractice litigation is a sick joke, a roulette game rigged so that plaintiffs and their lawyers' numbers come up all too often, and doctors and the honest people who pay in the end always lose"); Center for Justice and Democracy, http://www.centerjd.org (last visited May 31, 2006) (providing many articles and reports related to the center's efforts to fight tort reform).

The present Article extends that research further by comparing two sets of cases in which the payment to the claimant equaled or exceeded $1 million. The first group involves cases that were tried to juries. We systematically compare the verdict with the amount the insurer actually paid. We also go a step further and examine the nature of the injury, including the medical treatment sought and the alleged cause of the injury.

The second part of the Article examines a group of cases that were settled without a lawsuit. One of the most interesting findings from our earlier article is that of claims resulting in payments of $1 million or more, 10.1 percent were paid without pleadings of any kind. By contrast, only 7.5 percent of paid claims over $1 million followed a jury trial. Thus, while jury trials loom large in the public debate, the truly invisible cases—invisible in the sense that they evade the formal court system—constitute an even larger source of payments. We ask about the nature of pre-suit cases and compare them to the cases that went to trial and resulted in a plaintiff verdict.

Our approach to malpractice litigation issues in this paper involves qualitative as well as quantitative analyses. The qualitative analyses place a concrete face on the nature of the issues and the injuries experienced by patients involved in malpractice claims.

I. MILLION DOLLAR VERDICTS

Jury trials constitute only a very small part of medical malpractice payments. In 2005, the President of The Physician Insurers Association of America presented data indicating that jury verdicts for plaintiffs constituted only about 3 percent of malpractice payments. Our prior research in Florida showed that for cases involving payments of $1 million or more, just 7.5 percent followed a jury trial verdict. Further, during the fourteen-year period of the

7. In a future article, we will examine in more detail the roughly 82 percent of cases falling between these two extremes, that is, those settled after a lawsuit but before trial. For now, however, comparison of the two ends of the claims process—pre-suit cases and trial cases—allows for interesting comparisons that bear directly on the medical malpractice controversy.
8. Hearing Before the Civ. Law Comm., 93d Ill. Gen. Assemb. (2005) (testimony of Lawrence E. Smarr, President, Physical Insurers Association of America), available at http://www.ihatoday.org/issues/liability/talk/smarrest.pdf (providing an exhibit showing that paid claims constituted 25.2% of all claims and that plaintiff verdicts constituted 0.8% of this total).
9. Id.
study, 34 cases involved payments of $5 million or more. Of these 34, only two were decided by juries.\textsuperscript{10}

\textbf{A. Verdicts and Settlement Payments}

Although litigators are aware that cases often settle for less than verdicts, documenting the differences between the two has proved largely elusive because of the confidentiality of post-trial settlements. Nevertheless, there have been some prior studies. Broeder,\textsuperscript{11} researchers at the RAND Corporation,\textsuperscript{12} and The National Center for State Courts\textsuperscript{13} documented reductions in awards involving a mix of tort cases. Merritt and Barry conducted a detailed examination of jury awards in Franklin County (Columbus) Ohio and documented post-trial reductions in those awards.\textsuperscript{14} For example, a $12 million award was reduced by the trial judge to $8.5 million and a $3 million award was reduced by an appeals court to $1.5 million.

Four studies have specifically looked at reductions in medical malpractice verdicts. One study of malpractice verdicts in New York, Florida, and California examined reductions in “outlier” awards.\textsuperscript{15} Some of the largest malpractice awards in New York ultimately resulted in settlements between 5-10 percent of the original jury verdict.\textsuperscript{16} Similar findings were documented in a Pennsylvania study.\textsuperscript{17} Recent research on jury verdicts in Cook and DuPage counties in Illinois produced similar findings.\textsuperscript{18} On average, final payments to the Illinois plaintiffs were 42 percent lower than the jury verdict. In many cases the prevailing plaintiff settled for the policy limits of the health provider’s liability insurance. In the present symposium, Silver and Hyman present data from Texas closed claims

MILLION DOLLAR MALPRACTICE CASES

that show substantial differences between verdicts and ultimate payments showing that, on average, the larger the verdict, the smaller the percentage that the plaintiff recovered from the verdict.\(^{19}\)

With the exception of the Silver and Hyman research, previous studies used samples that were not necessarily representative of the universe of cases. In many instances multiple health care providers are named in a single lawsuit, complicating calculation of the total amount received by the plaintiff. Sometimes, defendants settle with a payment in advance of trial. The studies could not systematically account for such payments and thus may have underestimated eventual payments by some unknown degree.\(^{20}\) Prior studies, including the Hyman and Silver research, lacked information about the alleged cause of the injury and specifics of the injury itself, including the financial consequences for the injured person. Fortunately, in many cases the Florida closed claim data provide important insights about these other aspects of claims.

B. The Florida Data

In the previous research with the Florida closed claim database we relied on electronic files obtained from the Florida Department of Insurance. The present research is based on hard copies of more than 800 cases involving payments equal to or more than $1 million from which the electronic files were constructed, including a few cases that were not recorded in our original database and a few that extended into the first quarter of 2004.

We discovered that the hard files contained information that was more detailed than data recorded in the electronic files, including information about other defendants in the case. This allowed us to search for additional payments by these other defendants. Information about payments from excess insurance policies was found for some reports. In addition, there was usually a prose description of the medical treatment sought by the defendant, the alleged nature of the malpractice, and the injury sustained by the patient. In some instances the reports also contained detailed information about structured settlements. The hard files contained 54 cases involving jury trials with subsequent payments of $1 million or more. A few of the older cases had copies of the actual jury verdict attached to the file.

\(^{19}\) David Hyman & Charles Silver, Medical Malpractice Litigation and Tort Reform; It's the Incentives Stupid, 59 VAND. L. REV. 1085 (2006).

\(^{20}\) See VIDMAR, supra note 18 (capturing additional payments in some cases; however, the information was missing in many others).
With the exception of the few reports with copies of the verdict sheet, the closed claim data do not report verdicts. Although the name of the patient is redacted from the file, the name of the health care provider on whose behalf payment was made is reported. Westlaw contains a database of jury verdict reports based primarily on the Florida Jury Verdict Reporter, and there are sometimes supplemental verdict reports from other sources. Using the defendant's name we searched the Westlaw databases to identify the case. The verdict reports were checked to ensure that they corresponded with the data in the closed claim files. Verdict reports also contain information about other defendants, how liability was apportioned between them, and the amount of the judgment, which sometimes differs from the verdict.

We discovered, however, that some of the closed claim cases were not in the verdict reports. Verdict reporters are commercial enterprises and, despite claims to be comprehensive, there are often omissions. Some trials outside of major cities may be missed. Even in metropolitan areas there are sometimes missing cases, especially when the verdict is appealed. When cases are appealed the complete file is usually sent to the appeals court. If the verdict reporter employee searches the court files while the case is on appeal, the documents, including the verdict, will be missing. It appears that verdict reporters do not engage in systematic follow-up. This fact required additional effort on our part to obtain information on the verdict.

In some instances a search of Westlaw's courts of appeals cases produced the sought-after information about the verdict. The strategy for the remaining missing-verdict cases was to search the archives of the major newspapers in the county in which the trial took place. Through these procedures we were able to identify verdicts in 50 of the 54 cases with $1 million payments.

In order to account for the total payments, in each case we identified the other doctors named in the lawsuit and searched the electronic files to determine if a payment had also been made on their behalf. We did find additional payments and added those into the sum of the settlement amounts.\(^1\)

Despite our diligence in attempting to provide a complete picture of each case, there are three limitations on the data set. First, by choosing $1 million settlements at their face value we did not adjust for inflation. It was not practical to adjust for inflation in

---

\(^1\) Some cases involved hospital residents as defendants. The files show that the hospital assumed liability for these doctors.
gathering the hard copies of closed claims. As a consequence, in this Article, it is not appropriate to compare changes in the number of $1 million settlements over time. In 1990 a settlement for $692,000 would be equal to $1 million in today's dollars. A 1995 settlement for $807,000 would be equivalent to a $1 million today. The fact that there may be fewer $1 million settlements in the first years covered in the data does not mean that there were fewer cases, only that a number of cases that would be $1 million cases today are likely missing.

Second, despite our efforts we did not manage to match all cases and verdicts. Thus, of fifty-five $1 million verdicts only fifty cases have both verdicts and settlements.

Third, there are some settlements that possibly were not reported in the closed claim files. Reporting is dependent on the care and integrity of the insurer. The Department of Insurance does not monitor reporting, and thus some cases may not have been reported by insurers, particularly if their corporate offices were offshore, rather than in Florida. In other instances, health care providers may have been self-insured and paid money to a plaintiff, but not reported it to the Department of Insurance. In still other instances an insurer of excess liability, especially if an offshore corporation, may not have reported a payment. The primary insurer is supposed to report excess insurance payments as well as any deductible paid by the provider, and in some instances these payments are contained in the closed claims data. We believe we have accounted for most excess insurer payments, but the data do not allow a statement of absolute confidence that we have captured every payment.

Both the closed claim files and the Westlaw verdict reports are publicly available information. However, as reported above, the closed claim reports omit the name of the patient to protect patient privacy, but the Westlaw reports have patient names as well as those of defendants. To accommodate the patient privacy concerns we have assigned arbitrary code names to the cases reported in the tables.

In most previous research in the literature on medical malpractice litigation the patient's injury has been reported only as a category code on what is called the NAIC scale. The scale ranges from 1, classified as a minor or emotional injury, up to 8, denoting a grave injury; a 9 is death. This code system, while useful for certain

22. Neil Vidmar et al., Uncovering the "Invisible" Profile of Medical Malpractice: Insights from Florida, 54 DePAUL L. REV. 315, 327 n.88 (2005). The NAIC Scale was created by the International Standards Organization for statistical reporting on the closed claims studies they conduct for the National Association of Insurance Commissioners. The scale is as follows:

1: Emotional Only - Fright, no physical damage.
purposes, does not allow scrutiny of the actual injury for which the jury decided damages. Our analysis of the claims went further. Malpractice injuries occur after a person seeks treatment for a pre-existing illness or injury. The alleged malpractice occurs during treatment. As a consequence, we report short prose summaries of the original medical treatment sought by the plaintiff, the alleged malpractice, and the injury sustained by the plaintiff. These prose summaries were derived from the closed claims and the Westlaw summaries. The Westlaw files had more information about such matters as apportionment of liability between multiple defendants, remittitur, and apportionment of responsibility to the plaintiff, as well as breakdowns of the elements of the damages. The two sources were consistent in the description of the case.

For some cases our data allowed further exploration of the extent of injuries and the financial consequences of those injuries. The closed claim files also report when parties agree to a structured settlement that involves part or all of the money being put into an annuity. When structured settlements do occur the closed claims data report the amount of cash settlement, the amount the insurer paid for the annuity, and the total expected payments to the plaintiff from the annuity. This allows an estimate of the financial losses of the injured patient. In cases involving death, the annuity information often contains reports of how the structured settlement provides for a patient’s minor children. Structured settlements were reported more often in the pre-suit claims described in the next section, but those in the verdict cases also help to explain the economic basis of settlements.

4: Temporary: Major - Burns, surgical material left, drug side effect, brain damage. Recovery delayed.
5: Permanent: Minor - Loss of fingers, loss or damage to organs; includes non-disabling injuries.
6: Permanent: Significant - Deafness, loss of limb, loss of eye, loss of one kidney or lung.
7: Permanent: Major - Paraplegia, blindness, loss of two limbs, brain damage.
8: Permanent: Grave - Quadriplegia, severe brain damage, lifelong care or fatal prognosis.
9: Permanent: Death.
C. Verdicts and Settlements

What are the claim issues in $1 million verdicts? How do final settlements compare with the verdicts? Table 1 reports the treatment sought, the alleged basis of malpractice, the injury, and the severity according to a NAIC code scheme. It also reports the verdict, the total settlement amount, and a percentage representing the ratio of the total settlement to the verdict.

</table>
Table 1 shows that the number of male and female plaintiffs is roughly equal, twenty-six females versus twenty-four males. Ages of plaintiffs are missing in a few instances but they range from birth (coded as 0) to seventy-one. There are only three verdicts involving an alleged birth injury, although an additional three cases involve children less than seven years of age.
The original basis for seeking medical treatment varied from complaints of pain or other abnormalities in function, to surgery to correct an existing illness and life-threatening events such as a car accident or a heart attack. The seventh column in Table 1 describes the alleged cause of the injury. Reading those descriptions gives an important picture of the alleged acts of malpractice. Each description is accompanied by a letter or letters in bold. We classified each alleged cause as falling primarily into one of three categories: failure to diagnose or misdiagnose = D; treatment error = T; or failure to monitor = M.23 Four claims involved both failure to diagnose and treatment error, and one involved treatment and failure to monitor. Thus in the fifty cases there were a total of fifty-five errors. Using fifty-five as the base we can conclude that 42 percent of the claims in Table 1 involved diagnostic error claims, 51 percent involved treatment claims and 7 percent involved failure to monitor the patient following treatment.

Table 1 shows that the injuries incurred by defendants in these trial cases had very serious resultant medical problems or died. Using the NAIC Scale we find that 34 percent of cases involved death; 18 percent involved grave injuries like quadriplegia or severe brain damage; 26 percent involved major permanent injuries such a paraplegia or blindness; 16 percent involved permanent major injuries like deafness, loss of an eye, kidney or lung; 16 percent involved permanent damage to major organs; and 6 percent involved permanent “minor” damage such as loss of fingers or organs. While useful as a quick quantitative measure, the NAIC Scale obscures the actual details regarding the nature of the physical injuries.

The summary prose descriptions of the injuries reported in Table 1 provide a more useful look at what was involved. The seventeen deaths reported in Table 1 indicate that in some instances the patient did not die immediately. For example, case C v. G (1991) involved the death of a woman from sepsis five months after delivery of her baby. Not shown in the table is the information that the woman was survived by her infant. Case SB v. I (1993) involved a patient in a vegetative state for many weeks before death. Case S v. W (1995) shows a slow death over many months. The nine NAIC Category Eight cases involved grave injuries and speak for themselves. Some injuries characterized by the insurer as Category Seven (permanent major) leave questions about whether the injury should have been categorized as an Eight. Consider Case K v. W (1996). The patient

---

23. Dr. Lee, the physician co-author of this Article, made the classifications; the first author, Vidmar, served as a reliability check on the classifications.
was paralyzed on her left side, required bladder catheterization and assisted living. Case C v. D & H (1991) involved a stroke, loss of bladder and bowel control with confinement to a wheel chair. Injuries categorized as a Six or a Five according to the NAIC Scale may have had serious economic consequences for the patient. Amputation of a leg or a damaged organ or limb can affect employment and other factors associated with living. Many of the defendants in these cases may have contested liability, but if we assume liability was present, the $1 million verdicts can be very arguably seen as warranted by the actual injuries experienced by the plaintiffs.

The last three columns of Table 1 report the verdict and judgment, the final settlement, and the percentage of the verdict represented by the final settlement. In seven of the fifty cases the settlement exceeded the verdict. There are two related explanations for the payments in excess of verdicts. All of these excess payment cases were appealed. The plaintiff is entitled to post-judgment interest if the case is settled or affirmed on appeal and six of the seven reflect that interest. The 1991 case of C v. G is an anomalous case that resulted in the settlement being over six times the verdict. The mother died while delivering her child. The original jury verdict was $167,384 and the judge reduced the payment to $142,384 with a $25,000 setoff from a pre-trial settlement by one of the defendants. The case was appealed and the higher court ruled that the facts of the case showed that the jury verdict was "grossly inadequate" to the surviving child and her grandparents. In addition the court ruled that the trial judge had erred in excluding certain evidence. The case was sent back for retrial but the defendants settled for slightly over $1 million.

An important question is what percentage of the verdict is represented by the settlement. For purposes of calculation, the seven cases in which the ultimate payment was greater than the verdict were treated as equal to 100 percent since post-judgment interest explains the difference for all but case C v. G. Table 1 thus yields the conclusion that the defendants paid the full amount of the verdict in only ten of the fifty cases. In the remaining cases the final settlement amounts ranged from zero in N v. L (2002), where the judge rejected the award notwithstanding the jury verdict, through 19 percent to 97 percent. On average the final settlement was just 63 percent of the verdict. Consistent with previous research, the largest verdicts had the greatest reductions. Although the largest verdict, $10 million, was

---

24. In some cases, parties may contest the amount of damages rather than the question of liability.
paid in full, there were twelve additional verdicts that exceeded $4 million. Their average payout was 37 percent of the original verdict. Considering all cases there was a statistically significant negative correlation (-.39) between the size of jury verdict and the amount actually recovered in post-trial negotiations immediately after the verdict or during or following an appeal.25

One lesson from Table 1 confirms earlier research indicating that jury verdicts do not represent the end point in litigation but rather the continuation or beginning of a negotiation process on the settlement. Unlike previous research, the strength of the present data is that we believe that we have accounted for the sum of all payments made by defendants for a claim by a patient.

The final payments in all of these cases equaled or exceeded $1 million, sometimes several times over. A qualitative look at the actual injuries suffered by plaintiffs suggests that the final payments may have been reasonable given the injuries suffered. Two cases involved structured settlements but details of the agreement were not provided in the closed claims. In contrast, many pre-suit settlements provided detailed information about annuities that allow a perspective on projected losses and the reasons for them.

II. PRE-SUIT SETTLEMENTS

One of the most intriguing findings from our previous research on Florida closed claims was that 10.1 percent of settlements involving payments of $1 million or more were closed without a lawsuit being filed.26 Presumably the health care provider did not contest liability. What was the nature of the treatment sought? What were the grounds of the malpractice claims? What kinds of injuries were suffered and how serious were they? Finally, how did these pre-suit settlements claims differ from cases tried by juries?

Our methodological approach to gathering this data was similar to our approach to the jury trial cases. The closed claim files listed other defendants named in the claim. We first attempted to match those names with names in the hard copies of the files. If no match was found we searched the electronic database, which contains all payments, including those less than $1 million. If no matches were found in either of these sources we assume that no other payment was made. As mentioned in the beginning of this Article, the weakness in

25. Pearson r = -.39, t = 2.87 (df = 1,49), p < .05.
26. Parties settled an additional 4.6% of cases through pre-suit arbitration. This Article does not consider these claims.
this assumption is that some payments may not be recorded in the database if the insurer or self-insured health care provider did not submit a report to the Department of Insurance.

The hard copies of the files also included many instances in which a claim against a hospital included the names of doctors, nurses, pharmacists, or technicians. Often there was a notation that the claim was closed on behalf of those providers as well as the hospital. Many doctors, especially those completing their residencies, are considered employees of the hospital and thus were covered under the same insurance umbrella.

Table 2 reports the results of the 115 claims from 1990 through the first quarter of 2004 in which $1 million claims were paid without a lawsuit being filed.

</table>
Table 2 shows that 47 percent of the patients were female. Ages varied from birth to the seventies. For 46 percent of the claims the primary allegation was diagnostic error, with 47 percent being treatment error and 6 percent involving failure to monitor.

The patients often sustained severe injuries. The NAIC Scale calculations from Table 2 show that 42 percent of the cases resulted in deaths, 30 percent resulted in grave injuries, 20 percent resulted in major permanent injuries, and 8 percent involved lesser permanent injuries. Once again, however, it is important to read the summaries of the injuries and the alleged causes of the injuries, as described in Table 2, to appreciate the full gravity of the injuries suffered. Of course, neither the qualitative nor the quantitative data in Table 2 tell about the economic consequences to the patient or the patient’s heirs.

Before 1999, insurers were required to report whether a structured settlement was involved in the agreement and provide information about the nature of that settlement. It is not clear if all insurers complied with this requirement. In addition, details varied considerably for cases in which the data were reported. Of the 115

settlements in Table 2, thirty-one, or 27 percent, reported structured settlements. These cases are described in Table 3. The last column in that table reports the details of the settlement. In all of the cases there was a cash settlement and an annuity. In most instances the insurer reported the amount paid for the annuity and the projected amount that the patient would receive over the period of the annuity.

</tbody>
</table>

In some instances the estimated payments are staggering, reflecting medical costs to the patient, income losses, and/or financial support for surviving minor children. Case BMH (1991) was estimated at over $13 million; Case GBP (1994) was estimated at almost $9 million; Case DCH (1996) was estimated at almost $14 million. In CKR (1996), which the insurer rated only a Seven in terms of the level of injury, the estimated cost was almost $8 million, suggesting that the medical injury was more serious than reported, that the claimant had a large income loss, or a combination of both factors. Case HBM (1995) was estimated at over $16 million; and Case KCM (1997) was estimated at over $8 million.

It is noteworthy that during the same time period there were only two structured settlements reported in the jury trial cases contained in Table 1. In the 1991 case, C v. D & H, $1,500,000 of the $3,250,000 settlement was put into an annuity expected to yield a total payment of $2,954,347. In the 1996 case of Z v. H the $1 million
settlement involved a cash payment of $725,649 plus $482,351 for an annuity. However, it is likely that annuities were eventually purchased in other cases, although without direct input from the insurer. For instance, the 1992 case of R v. BR involved a deceased patient who left eight surviving children. Florida law, like many other state laws, requires the oversight and approval of a judge when money is awarded to minor children.\textsuperscript{27} Trial cases reflect an inability for the parties to agree on liability or amounts of damages and the adversarial nature of trial probably, in most instances, just excludes the insurer from participating in decisions about how the money is to be used.

The other potentially interesting finding from Table 3 is that it provides a rough guess as to how much plaintiff lawyers make from $1 million settlements. In discussing these figures with several plaintiff lawyers their opinion was that the lawyers working on a contingency fee basis would take their fee percentage only from the cash portion of the settlement. Thus, for example, if a $3 million settlement resulted in the purchase of a $2 million annuity plan, a lawyer working on a one-third contingency fee would receive her cut only from the cash portion of the remaining $1 million balance. This assumption, if correct, provides an important correction to claims about plaintiff lawyers getting huge profits from large cases. In this hypothetical example, rather than receiving $1 million from the $3 million settlement, the lawyer would receive only $333,333. The present research cannot confirm this assumption, but the data do raise an issue for additional research since windfall plaintiff lawyer fees often play an important role in claims about the need for tort reform.\textsuperscript{28}

\section*{III. JURY CASES AND PRE-SUIT CASES COMPARED}

Aside from the fact that pre-suit cases appear to have more structured settlements than trial cases, are there other characteristics that distinguish the two types of claim settlements?

We classified these claims according to whether they involved a claim against doctors, hospitals or both. Among awards/settlements from jury trials 64 percent of cases involved doctors alone, 4 percent

\textsuperscript{27} FLA. STAT. § 768.25 (2006).

involved hospitals alone and 33 percent involved doctors and hospitals. Among pre-suit settlements, only 38 percent involved doctors alone, 35 percent involved hospitals alone and 28 percent involved both doctors and hospitals. These differences were statistically significant. Thus, jury trials were more likely to involve doctors alone whereas pre-suit settlements were more likely to involve a hospital alone. The data do not provide an explanation as to why there are differences in these proportions. It is noteworthy, however, that in many of the pre-suit cases involving doctors and hospitals the hospital assumed liability for the doctors. This suggests that the doctors were engaged in medical residencies or were otherwise direct employees of the hospital.

A more important comparison involves the distribution of injury seriousness. For this comparison we add those five jury trial cases for which we could not find verdict data. The closed claim reports for these cases include the injury seriousness as well as the amounts actually paid in the post-verdict settlements. In addition, we can also ask if the amounts paid in settlements differed.

Table 4 reports the levels of injury seriousness according to the NAIC Scale, the percentage of cases falling within each category, and the mean amounts paid according to seriousness level.

<table>
<thead>

</tr>
</tbody>
</table>

Table 4 shows that the pre-suit cases involved a greater number of the most serious injuries compared to jury cases. A Chi-square comparison of the two distributions indicated that the

29. Chi-square = 20.4, df = 2, p < .01.
difference is statistically significant.\textsuperscript{30} Specifically, while 33 percent of jury cases involved death, 42 percent of pre-suit claims involved death; 16 percent of jury cases involved grave injuries whereas 30 percent of pre-suit claims involved grave injuries. Put another way, 72 percent of paid pre-suit claims involved grave injuries or death compared to 49 percent for jury trial cases.

Are there any differences in the amounts paid in relation to the level of injury seriousness? The last two columns of Table 4 show the amounts paid by level of seriousness and the mean amount over all levels of seriousness. There is no statistically significant difference between the overall mean amounts paid by insurers for jury cases and for pre-suit cases.\textsuperscript{31} Although the table shows some differences between levels Seven and Eight, the differences are not statistically significant across levels of seriousness.\textsuperscript{32}

**IV. SUMMARY AND CONCLUSIONS**

Discussion about problems with medical malpractice litigation tends to focus on jury verdicts, particularly large jury awards, even though jury awards represent only a small fraction of the total payouts by medical liability insurers. Previous research on a comprehensive set of closed medical malpractice claims submitted by Florida insurers showed that among cases involving payouts of $1 million or more, the number of cases settled without a lawsuit more than doubled the number of cases resulting in payouts following jury trial. In the present Article we analyzed and then compared these two sets of closed claims.

Consistent with previous research, jury trial cases tended to settle for substantially less than the original verdict. On average the settlement in $1 million cases was 67 percent of the verdict. With one exception, cases with verdicts over $4 million settled, on average, for 37 percent less than the verdict. Both the quantitative ratings and the qualitative data provided in the liability insurers' reports show that the injuries suffered by plaintiffs in jury trial cases were very serious. The injuries in claims settled without a lawsuit were comparable to jury trial cases. Presumably there was no serious dispute about liability in these pre-suit claims. A number of the pre-suit claim files also had information about structured settlements for the plaintiffs that support a picture of major medical or income losses

\textsuperscript{30} Chi-square $= 16.85$, $df = 4$, $p < .01$.

\textsuperscript{31} Analysis of variance: $F = .542$, $df = 1, 166$, $p = n.s.$

\textsuperscript{32} Analysis of variance: $F = 1.56$, $df = 5, 166$, $p = n.s.$
resulting from the injuries, either for the patients themselves or for their heirs.

The data analyses support a view that tort reform efforts focused on jury verdicts are misdirected, at least with respect to $1 million verdicts in Florida. Not only do jury trials constitute only a small portion of $1 million payments, the settlements following verdicts tend to be substantially less than the jury awards.

On their own and in comparison to $1 million claims settled without a lawsuit, the settlements following verdicts reflect payments for very serious economic losses. Recent assertions that $1 million claims have increased, perhaps even doubled, may or may not be true, but that does not necessarily mean that the awards were unwarranted. The present data suggest two possible alternative hypotheses. The first is that the cost of injuries due to medical errors may have increased in recent years. The second is that more patients are seeking redress for very serious negligent injuries. The findings in this Article present a prima facie argument that these alternative hypotheses may be valid. The $1 million settlement claims without a lawsuit further suggest that the focus in the medical malpractice reform debate should be on the basis and dynamics of settlement rather than trial.

33. See Dean Starkman, Calculating Malpractice Claims, WASH. POST, Dec. 29, 2005, at D1 (referencing uncited sources asserting that the percentage of claims in excess of $1 million among all claims has doubled to 8 percent over the past five years).

34. See Vidmar et al., supra note 5, at 338–45 (providing support for the hypothesis that more patients are seeking redress for very serious negligent injuries). Defendants paid more claims involving very serious injuries or death in Florida after the year 2000 than at the beginning of the 1990s.
